

10 multiple mobile users, said receiver device including an
11 adaptive chip equalizer capable of tracking said channel
12 response and adapting one or more equalizer taps of said
13 adaptive chip equalizer using said received pilot signal,
14 said adapting for minimizing received symbol errors;
15 wherein said receiver device de-spreads said
16 communications signal using a chipping sequence associated
17 with that mobile user to extract the information symbols
18 for that user from said single channel.

A
1 16. (New) The apparatus as claimed in Claim 15, wherein a
2 power for a transmitted pilot signal is equal to the power
3 transmitted for each user.

1 17. (New) The apparatus as claimed in Claim 16, wherein as
2 power for a transmitted pilot signal increases, a power
3 transmitted for each mobile user decreases for the same
4 total transmitted power.

1 18. (New) The apparatus as claimed in Claim 15, wherein
2 said means for generating a pilot signal further generates
3 a plurality of pilot sequences each having a known chipping
4 sequence and transmits said plurality of pilot signals
5 simultaneously with said communications signal over said
6 single channel, said mechanism for adapting one or more
7 equalizer taps of said adaptive chip equalizer using each
8 said received pilot signals.

1 19. (New) The apparatus as claimed in Claim 18, wherein
2 said adapting mechanism executes at a greater speed using
3 when adapting said adaptive chip equalizer based on said

4 received plurality of pilot signals as compared to when
5 adapting based upon a single pilot signal, whereby said
6 plurality of pilots enable efficient tracking of fast
7 varying channels.

1 20. (New) The apparatus as claimed in Claim 15, wherein
2 said pilot signal is transmitted continuously, said
3 receiver device capable of performing continuous equalizer
4 adaptation.

AI
1 21. (New) A receiver for a communications system capable of
2 receiving a communications signal including multiple
3 information symbols comprising data sequences destined for
4 multiple users simultaneously over a single channel having
5 a channel response, said communications signal including a
6 pilot signal having a known chipping sequence, said
7 receiver comprising:
8 an adapting chip equalizer used for simultaneously
9 receiving said communications signal and pilot signal and,
10 obtaining an equalizer output; and
11 a device for de-spreading said equalizer output to
12 obtain a data sequence for a particular user;
13 wherein one or more equalizer taps of said adaptive
14 chip equalizer are adapted using said received pilot
15 signal, said de-spreading device de-spreading said
16 communications signal using a chipping sequence associated
17 with that user to extract the information symbols for that
18 user from said single channel.

1 22. (New) The receiver according to Claim 21, wherein said
2 communications signal includes a plurality of pilot

3 sequences each having a known chipping sequence for
4 transmission simultaneously with said communications signal
5 over said single channel, said adapting chip equalizer
6 adapting one or more of its equalizer taps using each said
7 received pilot signal.

AI
1 23. (New) The receiver according to Claim 22, wherein said
2 adapting chip equalizer operates at a greater speed using
3 when adapting based on said received plurality of pilot
4 signals as compared to when adapting based upon a single
5 pilot signal, whereby said plurality of pilots enable
6 efficient tracking of fast varying channels.

1 24. (New) The receiver according to Claim 21, wherein said
2 pilot signal is transmitted continuously for enabling
3 continuous equalizer adaptation.--
